Defining Classes and Methods

Chapter 5b

Information Hiding

- Programmers using a class method need not know details of implementation
 - Only needs to know *what* the method does
- Information hiding:
 - Designing a method so it can be used without knowing details
- Also referred to as *abstraction*
- Method design should separate *what* from *how*

The **public** and **private** Modifiers

- Type specified as **public**
 - Any other class can directly access that object by name
- Classes generally specified as **public**
- Instance variables usually not **public**
 - Instead specify as **private**

Programming Example

- Demonstration of need for private variables
- Download **Rectangle**
- Statement such as
box.width = 6;
is illegal since width is **private**
 - Keeps remaining elements of the class consistent in this example

Programming Example

- Another implementation of a Rectangle class
- Download **Rectangle2**
- Note **setDimensions** method
 - This is the only way the **width** and **height** may be altered outside the class

Accessor and Mutator Methods

- When instance variables are private the class must provide methods to access values stored there
 - Typically named **getSomeValue**
 - Referred to as an accessor method
- Must also provide methods to change the values of the private instance variable
 - Typically named **setSomeValue**
 - Referred to as a mutator method

Accessor and Mutator Methods

- Consider an example class with accessor and mutator methods
- Download **SpeciesFourthTry** and **SpeciesFourthTryDemo**
- Note the mutator method
 - **setSpecies**
- Note accessor methods
 - **getName, getPopulation, getGrowthRate**

Methods Calling Methods

- A method body may call any other method
- If the invoked method is within the same class
 - Need not use prefix of receiving object
- Download **Oracle** and **OracleDemo**

Encapsulation

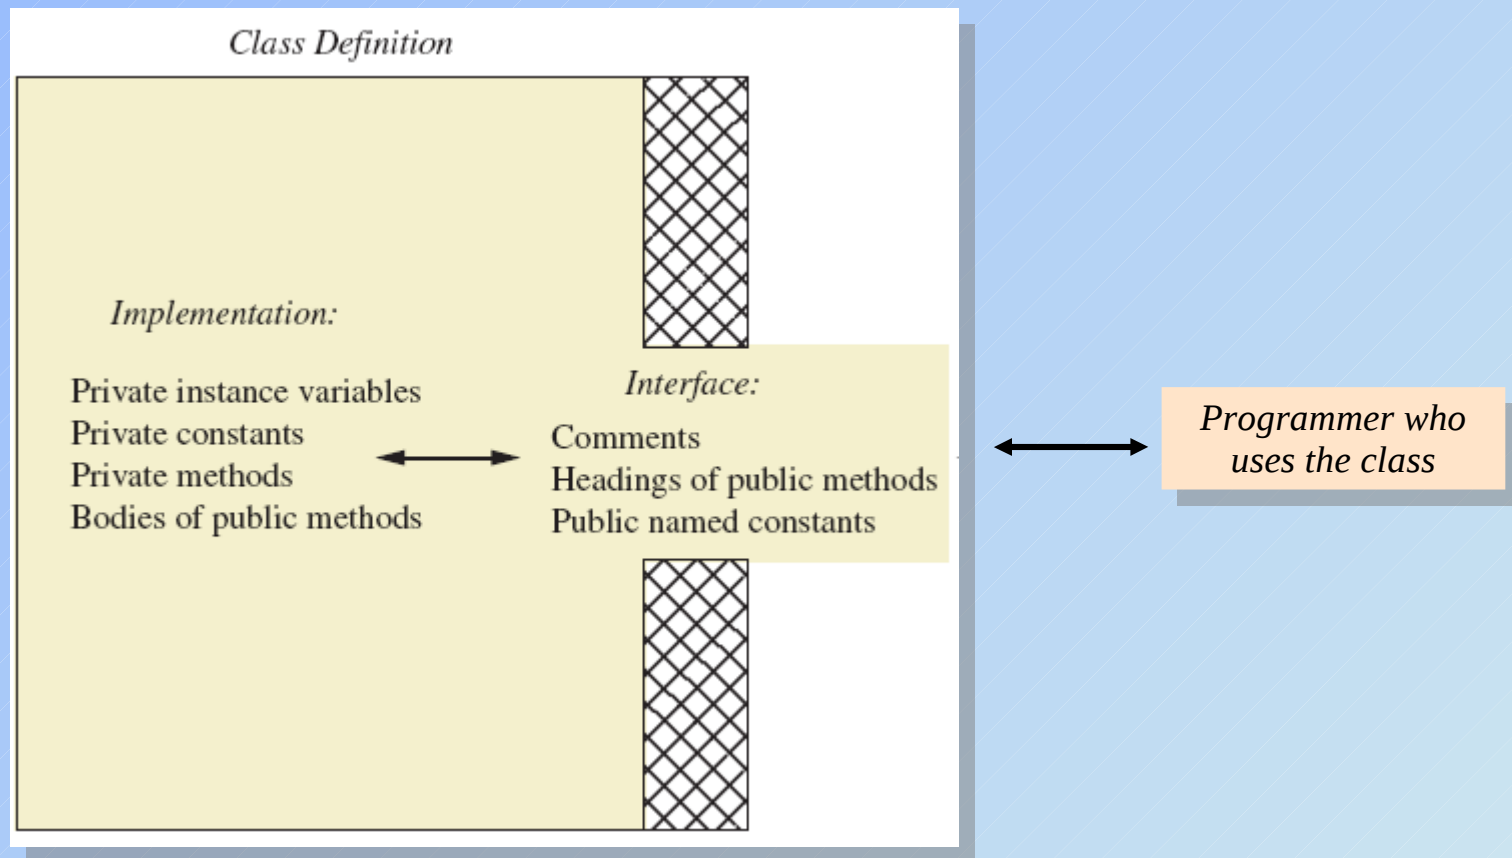

- Consider example of driving a car
 - We see and use break pedal, accelerator pedal, steering wheel – know what they do
 - We do not see mechanical details of how they do their jobs
- Encapsulation divides class definition into
 - Class interface
 - Class implementation

Encapsulation

- *A class interface*
 - Tells what the class does
 - Gives headings for public methods and comments about them
- *A class implementation*
 - Contains private variables
 - Includes definitions of public and private methods

Encapsulation

- Figure 5.3 A well encapsulated class definition

Encapsulation

- Preface a class definition with comment on how to use class.
- Declare all instance variables in the class as private.
- Provide public accessor methods to retrieve data.
- Provide public methods manipulating data.
 - Such methods could include public mutator methods.
- Place a comment before each public method heading that fully specifies how to use the method.
- Make any helping methods private.
- Write comments within class definition to describe implementation details.

Automatic Documentation **javadoc**

- Generates documentation for class interface
- Comments in source code must be enclosed in `/** */`
- Utility **javadoc** will include
 - These comments
 - Headings of public methods
- Output of **javadoc** is HTML format

Automatic Documentation **javadoc**

- Add **javadoc** comments to the **Rectangle** class
- In drjava
 - Tools -> Javadoc -> Preview Javadoc for Current Document
 - May have to set browser first:
 - Edit -> Preferences -> Resource Locations
 - Enter browser command (firefox,...)

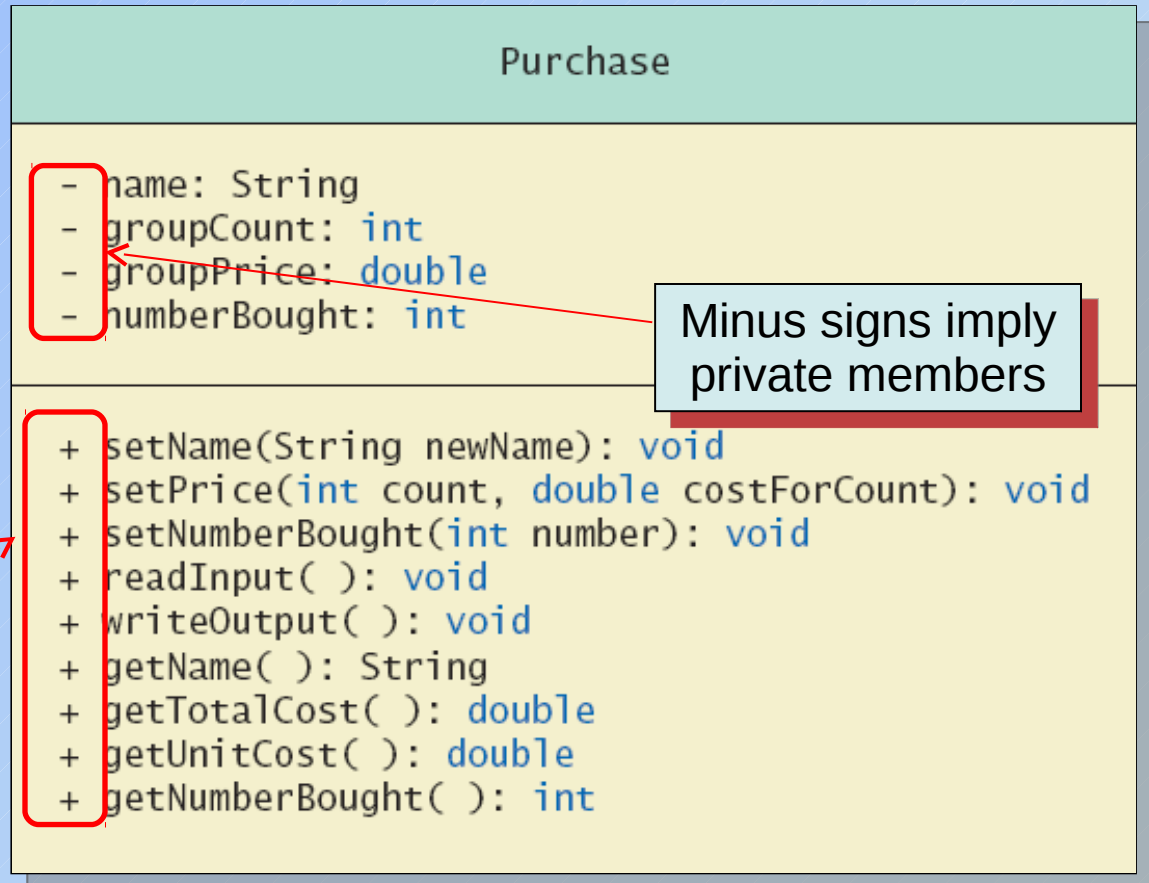

UML Class Diagrams

- Recall Figure 5.2, a class outline as a UML class diagram

UML Class Diagrams

- UML for a **Purchase** class

Plus signs imply public members

Minus signs imply private members

UML Class Diagrams

- Contains more than interface, less than full implementation
- Usually written *before* class is defined
- Used by the programmer defining the class
 - Contrast with the interface used by programmer who uses the class

Objects and References: Outline

- Variables of a Class Type
- Defining an equals Method for a Class
- Boolean-Valued Methods
- Parameters of a Class Type

Variables of a Class Type

- All variables are implemented as a memory location
- Data of *primitive type* stored in the memory location assigned to the variable
- Variable of *class type* contains memory address of object named by the variable

Variables of a Class Type

- Object itself not stored in the variable
 - Stored elsewhere in memory
 - Variable contains address of where it is stored
- Address called the *reference* to the variable
- A *reference type* variable holds references (memory addresses)
 - This makes memory management of class types more efficient

Variables of a Class Type

- Behavior of class variables

```
SpeciesFourthTry klingonSpecies, earthSpecies;
```

klingonSpecies

?

...

earthSpecies

?

Two memory locations for the two variables

```
klingonSpecies = new SpeciesFourthTry();  
earthSpecies = new SpeciesFourthTry();
```

klingonSpecies

2078

...

earthSpecies

1056

⋮

⋮

1056

?

?

?

...

2078

?

?

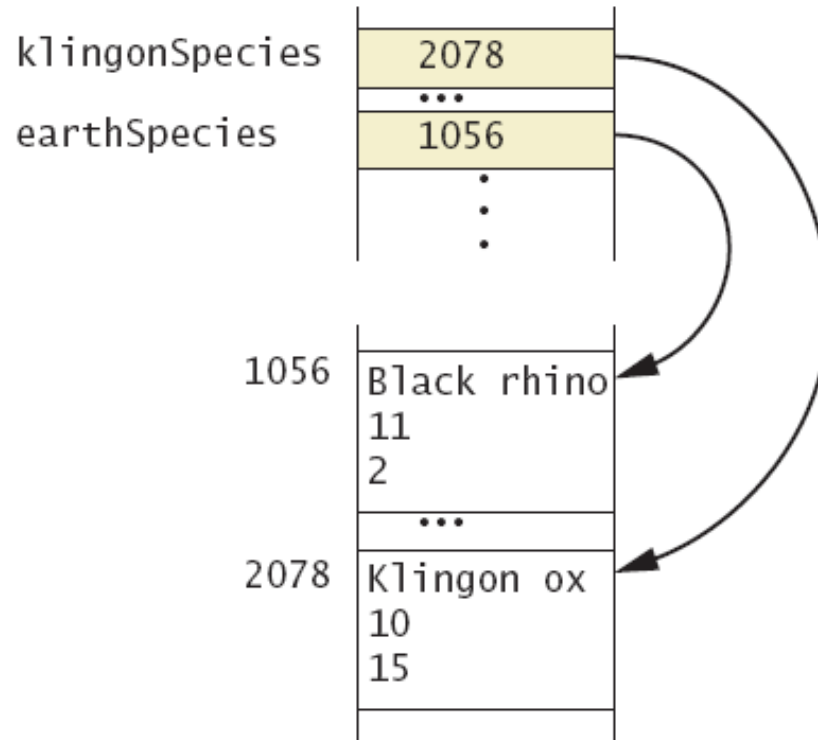

?

We do not know what memory addresses will be used. We used 1056 and 2078 in this figure, but they could be almost any numbers.

Variables of a Class Type

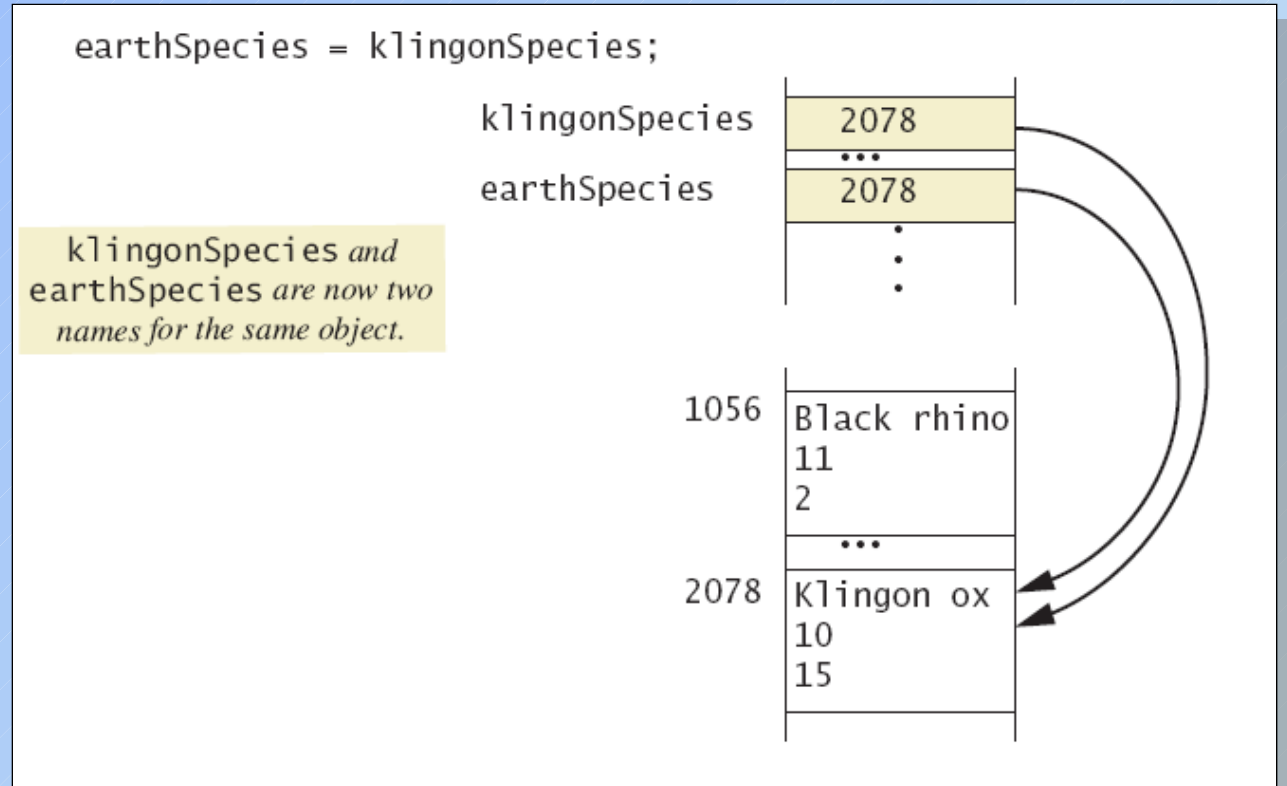

- Behavior of class variables

```
klingspecies.setSpecies("Klingon ox", 10, 15);  
earthSpecies.setSpecies("Black rhino", 11, 2);
```

Variables of a Class Type

- Behavior of class variables

Variables of a Class Type

- Behavior of class variables

```
earthSpecies.setSpecies("Elephant", 100, 12);
```

klingsonSpecies

2078

earthSpecies

2078

This is just garbage that is not accessible to the program.

1056

Black rhino

11

2

...

2078

Elephant

100

12

Variables of a Class Type

- Dangers of using `==` with objects

```
klingsonSpecies = new SpeciesFourthTry();  
earthSpecies = new SpeciesFourthTry();
```

klingsonSpecies

2078

...

earthSpecies

1056

⋮

1056

?

?

?

...

2078

?

?

?

We do not know what memory addresses will be used. We used 1056 and 2078 in this figure, but they could be almost any numbers.

Variables of a Class Type

- Dangers of using `==` with objects

```
klingspecies.setSpecies("Klingon ox", 10, 15);  
earthSpecies.setSpecies("Klingon ox", 10, 15);
```

```
if (klingspecies == earthSpecies)  
    System.out.println("They are EQUAL.");  
else  
    System.out.println("They are NOT equal.");
```

The output is They are Not equal, because 2078 is not equal to 1056.

Defining an `equals` Method

- As demonstrated by previous figures
 - We cannot use `==` to compare two objects
 - We must write a method for a given class which will make the comparison as needed
- Download `Species` and `SpeciesEqualsDemo`
- The `equals` for this class method used same way as `equals` method for `String`

Boolean-Valued Methods

- Methods can return a value of type **boolean**
- Use a **boolean** value in the **return** statement
- Add this method to the **Species** class

```
/**  
    Precondition: This object and the argument otherSpecies  
    both have values for their population.  
    Returns true if the population of this object is greater  
    than the population of otherSpecies; otherwise, returns false.  
*/  
public boolean isPopulationLargerThan(Species otherSpecies)  
{  
    return population > otherSpecies.population;  
}
```

Parameters of a Class Type

- When assignment operator used with objects of class type
 - Only memory address is copied
- Similar to use of parameter of class type
 - Memory address of actual parameter passed to formal parameter
 - Formal parameter may access public elements of the class
 - Actual parameter thus can be changed by class methods

Programming Example

- Download **DemoSpecies**
 - Note different parameter types and results
- Download **ParametersDemo**
 - Parameters of a class type versus parameters of a primitive type
